**NOTE:** This is simplified. However, it's a useful high-level model for determining what kind of database you need for your project.

## Data models

- **Documents:** Single type of thing, no relations
- **Relational:** Multiple types of things, relations between different types of things
- **Graph:** Single or multiple types of things, relations between different things of the *same* type

## Consistency models

- **Strong consistency:** There is a single canonical view of the database, and everything connecting to any node in the database cluster is guaranteed to see the same data at the same moment in time.
- **Eventual consistency:** There can be multiple different views of the database (eg. different nodes in the cluster may have a different idea of what the current state of the data is), but once you stop changing stuff, they will eventually converge into a single view.
- **No consistency:** There's no guarantee that all nodes in the cluster will ever converge to the same view, whatsoever.

## Schemafulness

- **Schemaful:** You know the format (fields, types, etc.) of the data upfront. Fields may be optional, but every field you use is defined in the schema upfront.
- **Schemaless:** You have no idea what the format is going to be. This is rarely applicable, and only really applies when dealing with storing data from a source that doesn't produce data in a reliable format.
